

## **Literaturübersicht für die 3. Revision der GA1-Leitlinie; Zeitraum 2016-2021 (alphabetische Reihenfolge)**

### **Einteilung des Evidenzniveaus nach SIGN:**

- Level 1++.** Hochwertige Meta-Analysen, systematische Reviews von randomisierten, kontrollierten Studien (RCT) oder RCT mit einem sehr niedrigen Bias-Risiko
- Level 1+.** Gut durchgeführte Meta-Analysen, systematische Reviews von randomisierten, kontrollierten Studien (RCT) oder RCT mit einem niedrigen Bias-Risiko
- Level 1-.** Meta-Analysen, systematische Reviews von randomisierten, kontrollierten Studien (RCT) oder RCT mit einem hohen Bias-Risiko
- Level 2 ++.** Hochwertige systematische Reviews von Case/Control- oder Kohortenstudien  
Hochwertige Case/Control- oder Kohortenstudien mit einem sehr niedrigen Risiko für Confounder-Effekt oder Bias und mit der hohen Wahrscheinlichkeit für eine kausalen Beziehung
- Level 2+.** Gut durchgeführte Case/Control- oder Kohortenstudien mit einem niedrigen Risiko für Confounder-Effekt oder Bias und mit der mittleren Wahrscheinlichkeit für eine kausalen Beziehung
- Level 2 -.** Case/Control- oder Kohortenstudien mit einem hohen Risiko für Confounder-Effekt oder Bias und mit einem signifikanten Risiko, dass die dargestellte Beziehung nicht kausal ist.
- Level 3.** Nicht-analytische Studien, z. B. Einzelfallberichte, Fallserien.
- Level 4.** Expertenmeinung

Author	Title	Study Design	Patients (n)	Clinical endpoints	Results / Conclusions	Bias (according to GRADE)	Confounding (according to GRADE)	SIGN Level	Group (Diagnostic, Therapeutic, Monitoring)
Abdul Wahab et al. (2016) Biomed Res Int; 2016:4074365	Clinical and Mutational Analysis of the GCDH Gene in Malaysian Patients with Glutaric Aciduria Type 1	Case series	n=7	Clinical outcome Neuroimaging Mutation analysis	<p><u>Clinical outcome</u>: all patients were symptomatic, onset at age 3 to 11M (n=3 with acute onset, n=2 with insidious onset, n=2 with SDH), age at diagnosis 6M to 13Y. Symptoms: severe motor disability + absence of speech (n=5 patients), moderate disability + ability to walk with assistive device + normal school with educational support (n=1), mild motor impairment (n=1, age 2Y).</p> <p><u>Neuroimaging</u>: widening of bilateral Sylvian fissures with frontotemporal atrophy in all patients (except 1 patient with generalized cerebral atrophy).</p> <p><u>Treatment</u>: Upon diagnosis in all patients: low protein diet supplemented with lysine / tryptophan-free synthetic formula and L-carnitine.</p> <p><u>n=3 novel mutations</u> (Gln76Pro, Glu131Val, Gly390Trp).</p> <p><u>n=8 missense mutations</u> (Gln76Pro, Glu131Val, Ala298Thr, Gly354Ser, Arg355Cys, Arg386Gln, Gly390Trp, Ala421Thr),</p> <p><u>n=1 nonsense mutation</u> (Arg128*),</p> <p><u>n=1 splice site mutation</u> (c.1244-2A&gt;C).</p> <p><u>n=2 homozygous</u> (Gln76Pro, Arg386Gln) in patients with parental consanguinity. All mutations were predicted to be disease causing by MutationTaster2.</p>	Detection bias (low n)	Indirectness (population differences)	2-	Diagnostik

<b>Abid et al.</b> (2021) Ann Emerg Med 17:S0196-0644(21)00298-5	Risk of Traumatic Brain Injuries in Infants Younger than 3 Months With Minor Blunt Head Trauma	Secondary analysis of public use data set from PECARN's prospective observational study	n=1081 patients <3 months old	Traumatic brain injury after minor head trauma	➔ " The PECARN traumatic brain injury low-risk criteria accurately identified infants <3 months old at low risk of clinically important traumatic brain injuries. However, infants at low risk for clinically important traumatic brain injuries remained at risk for traumatic brain injuries on CT, suggesting the need for a cautious approach in these infants. "	No patients with GA1 included	Indirectness (population differences)	2-	Monitoring
<b>Alaei et al.</b> (2020) Iran Biomed J. 2020 May;24(3):201-5	Once in a Blue Moon, a Very Rare Coexistence of Glutaric Acidemia Type I and Mucopolysaccharidosis Type IIIB in a Patient	Case report	n=1	Mutation analysis	- 4Y boy with <u>first-cousin parents</u> . - Symptoms: <u>Macrocephaly, developmental delay</u> , speech problem, complaints of hyperactivity and concentration problem, falling down when walking, turricephaly, hepatomegaly, wrist weakness, prolonged diarrhea, broad nasal bridge, low-set ears, short palate, macular edema, short Achilles tendons. - 5M: <u>bilateral arachnoid cysts</u> in temporal lobes with extension to Sylvian fissure and increased subarachnoid space over convexities. - 14M: <u>trauma</u> ➔ number of spoken words decreased - <u>two homozygous likely pathogenic variants</u> in NAGLU (c.625A>C; p.Thr209Pro) and GCDH (c.1298C>T; p.Ala433Val) genes confirmed coexistence of GA1& MPSIIIB.	Detection bias (small sample size)	Indirectness (population differences)	3	Diagnosis
<b>Astrand et al</b> (2016) BMC Med; 14:33.	Scandinavian Neurotrauma C. Scandinavian guidelines for initial management of minor and moderate head trauma in children	Guideline	Review		Minor head trauma (80-90%) = Oberbegriff für minimal & mild (& moderate) head trauma (s.u.)  ➔ <i>Patients with mild head injury + normal neurological examination + initial head CT without any pathological findings related to the head trauma can be discharged (Evidence grade: low evidence, Recommendation: weak)"</i>	No patients with GA1 included		2++	Monitoring
<b>Bekiesinska-Figatowska et al.</b> (2021) BMC	Increasing the spectrum of white matter diseases with tigroid	Case report	N=1	MR imaging	Patient with glutaric aciduria, identified by metabolic workup due to developmental delay. Follow-up over 9 years. Appropriate diet and	Detection bias (small sample size)	Case report	3	Monitoring

Pediatrics; 21:146	pattern on MRI: glutaric aciduria type 1 – case report				supplementation, deficits in specific cognitive skills. 3 MR scans at 8M, 21M, 10Y. Scan 1+2: diffusion restriction in the fornix. Scan 3: “tigroid pattern”: radially oriented stripes of low (relatively normal) signal intensity are observed within diffusely affected T2-hyperintense cerebral white matter.		Imprecision (low n of patients)		
<b>Bernstein et al.</b> (2020) Nutrients ; 12 :3162.	Inconsistencies in the Nutrition Management of Glutaric Aciduria Type 1: An International Survey	22-question survey	0 (n=300 health care professionals were asked to respond to the questions, n=66 participated)	Nutrition management	66 dietitians responded, - of which 58 practice in the US / 18 outside of the US; - 57 manage patients identified by NBS, 40 after striatal injury, 26 with late-onset GA1. 1. <6Y, identification through NBS. - Breastfeeding: clinicians allowed feeding at the breast (50%), expressed breastmilk (20%), did not recommend (10%), other (20%). - Medical food: recommended by 87%. 13% did not recommend formulations containing amino acids of which 63% recommended protein restricted diet and 37% did not recommend any restriction (n=3 clinicians). - Counting intact protein: 76% count grams of protein from food, 20% count mg of lysine. 6% use “exchange” system. (patient-dependent: start with counting lysine, later count protein). - Arginine supplementation: not recommended by 95%. 2. Diet liberalization - Definition: “some restriction of food protein to provide the US dietary reference intake” (84%), reduction/elimination of medical food (46%/30%). No restriction of food protein (7%). - Age of diet liberalization: after age 6Y (27% with striatal injury; 45% without striatal injury); age 3Y (2%/2%); age 10Y (9%/12%); Never (20%/9%). - Protein-controlled diet: providing only the amount recommended by the US DRI (85%), certain amount of protein counted by the patient	Only US, and South American Centers included (selection bias)  No Amino acid data reported  Different opinions on and implementation of “protein-controlled diet”	Questionnaire	3	Monitoring

					(44%), meat / high biological value protein not allowed (27%). - Tracking protein intake: counting grams of protein (63%), counting "servings" of higher protein foods (20%), no counting at all / full liberalization (20%); depending on patient (7%). - Goals for plasma lysine concentration: before age 6Y low-normal (46%), after age 6Y normal (84%). - Diet monitoring: monitoring of plasma amino acids (before age 6Y 93%, after age 6Y 92%), anthropometrics (91%/ 88%), plasma 3OHGA (9% / 12%), neurocognitive status (23% / 34%).				
<b>Bessey et al. (2020)</b> Int J Neonatal Screen., 6:93	The Cost-Effectiveness of Expanding the UK Newborn Bloodspot Screening Programme to Include Five Additional Inborn Errors of Metabolism	Decision-tree model with lifetable estimates of outcomes, model structure and parameterisation informed by a systematic review and expert clinical judgment.		- National Health Service/Personal Social Services perspective - lifetime costs and quality-adjusted life years (QALYs) were discounted at 1.5%. - Uncertainty in the results was explored using expected value of perfect information analysis methods together with a sensitivity analysis using the screened incidence rate in the UK from 2014 to 2018.	The model estimates that screening for all the conditions is more effective and cost saving when compared to not screening for each of the conditions, and the results were robust to the updated incidence rates	)	key uncertainties: sensitivity and specificity of the screening test and the estimated costs and quality	3	Diagn ostik
<b>Biasucci et al. (2018)</b> Ital J Pediatr; 44(1):8	Early neonatal Glutaric aciduria type I hidden by perinatal asphyxia: a case report	Case report	n=1	Perinatal asphyxia Early post-natal onset of GA1	Male patient, born at term after prolonged labour. <u>Severe asphyxia + asystoly</u> soon after birth → cardiopulmonary resuscitation. 30 min after birth severe + <u>diffuse axial hypotonia</u> , increased muscular tone of the limb extremities, absence of crying + archaic reflexes. 90 min after birth: stuporous state with fixed gaze + epileptic	Detection bias (small sample size)	Imprecision (small sample size)	3	Diagn ostik

					seizures interrupted by Phenobarbital (recurrent on the first day of life). <u>Diagnosis of GA1 at d10</u> (enzyme activity + mutation analysis). Start of metabolic treatment (low lysine diet, lysine-free tryptophan-reduced infant formula, supplementation of riboflavin + L-carnitine). Severe encephalopathy with drug resistant epileptic seizures. CVC-related sepsis → exitus at 2y				
<b>Boucherau and Schiff (2020) J Nutr</b> 150 :2556S-2560S	Inherited Disorders of Lysine Metabolism: A Review	Review	0	Glutaric aciduria Antiquitin deficiency	Literature review of inherited disorders of lysine metabolism			3	
<b>Boy et al. (2017) Orphanet J Rare Dis;</b> 12(1):77	Extrastriatal changes in patients with lateonset glutaric aciduria type I highlight the risk of long-term neurotoxicity	Prospective multicentre observational trial	n=8 patients with late-onset GA1 + n=8 early-diagnosed patients with GA1 (=controls)	MRI: (1) frontotemporal hypoplasia, presence of abnormal (2) gray and/or (3) white matter signal, (4) space-occupying lesions	Progredient extrastriatal abnormalities in late onset patients (1) In all late-onset patients, in 3 controls (HE) (2) no patient with typical striatal changes. (3) in all late-onset patients, in 3 controls (HE) (4) in 6 late-onset patients (all patients except maternal GA1), 1 control	Detection bias (small sample size)	Small sample (Imprecision)	2-	Monitoring
<b>Boy et al. (2017) J Inherit Metab Dis;</b> 40(1):75-101	Proposed recommendations for diagnosing and managing individuals with glutaric aciduria type I: second revision	Guideline		Diagnostic approach Treatment Monitoring	18 recommendations and 5 statements			2++	Diagnostik  Therapie  Monitoring
<b>Boy et al. (2018) Ann Neurol;</b> 83(5):970-979	Newborn Screening: A Disease-Changing Intervention for Glutaric Aciduria Type 1	Prospective multicentre observational trial	<u>n=94 patients:</u> 87 identified by NBS (64 HE, 21	- Incidence of GA1 in Germany & sensitivity of NBS - Genotype-Phenotype-Correlation	<u>Estimated incidence:</u> 1:124.930 newborns, sensitivity of NBS: 95,6%. <u>Confirmation of diagnosis:</u> Positive NBS results were confirmed by GCDH gene analysis and/or enzyme activity analysis in 80/87 patients	Low risk. Large sample, 98% of patients identified by NBS in	Max. age at last visit: 17,75Y  Small sample of older children	2++	Diagnostik  Therapie

			<p>LE, 2 unknown), 4 missed by NBS (all LE), 3 maternal GA1 (all HE).</p> <p>- Neurologic outcome separated into 2 categories: 1. Major motor symptoms (manifestation of a movement disorder) 2. Minor motor symptoms (fine motor deficits and/or delayed achievement of motor milestones)</p> <p>- Maintenance treatment (MT) and intermittent emergency treatment (ET)</p> <p>- Renal outcome: GFR according to Schwartz</p> <p>- Survival</p>	<p><u>Genotype-Phenotype-Correlation (76 patients):</u> n=35 homozygous (32 HE, n=9 p.Glu365Lys, n=5 p.Arg402Trp), n=38 compound heterozygous (20 HE, 16 LE).</p> <p>Genotype predicts biochemical phenotype, but clinical phenotype is not predicted by genotype or biochemical phenotype.</p> <p><u>Treatment:</u> n=74 (85%) followed by smc, n=59 (68%) treated according to guideline recommendations. MT including carnitine supplementation resulted in best neurologic outcome. MT deviations comprised: Non-adherence to diet (n=8), inadequate dietary prescription (n=6), feeding problems (n=1), delayed start of MT (n=1).</p> <p><u>Neurologic outcome:</u> n=56 (64%) asymptomatic, n=31 (36%) neurologic symptoms (n=26 (30%) major motor symptoms (MD), n=5 (6%) minor motor symptoms). Polyneuropathy: n=0 patients.</p> <p><u>Major motor symptoms:</u> n=13 acute onset (n=11 following EC, n=2 after SDH), n=12 insidious, n=1 unknown.</p> <p>Less severe dystonia in patients with insidious onset.</p> <p><u>Impact of treatment on outcome:</u> Major motor symptoms: all patients without AET develop MD, 93% with adequate treatment remain asymptomatic.</p> <p>Non-adherence to MT (n=16): 50% dystonia (less severe, high frequency of insidious onset) plus 25% with minor motor symptoms.</p> <p><u>CKD:</u> Median GFR 123 (range 85-214). N=3/6 Pat. &gt;12Y: GFR &lt;90, N=2 intermitt. GFR &lt;60. N=1 acute renal failure through HUS.</p> <p>→ GFR declined with age regardless of neurologic phenotype, did not differ between HE / LE patients or treatment groups.</p> <p><u>Survival:</u> n=82 (93%) patients survived. 4/5 patients who died had dystonia (n=3 severe, n=1 moderate) following EC, 1 died during HUS. Lower</p>	<p>Germany during 1999-2016 are included.</p>	<p>Invasive infection with pneumococcus + HUS</p>		<p>Monitoring</p>

					life expectancy for patients with severe MD / acute onset MD. <u>Maternal GA1</u> : 2 mothers neurologically asymptomatic				
<b>Boy et al.</b> (2019) J Inherit Metab Dis; 42(1):117-127	Patterns, Evolution, and Severity of Striatal Injury in Insidious-Vs Acute-Onset Glutaric Aciduria Type 1	Case control study	<u>n=21 symptomatic patients</u> : n= 11 acute onset (n=2 LE, n=9 HE), n=10 insidious onset (n=2 with later acute onset) (n=2 LE, n=8HE).	MRI: striatal changes (localized / extensive signal changes, atrophy on visual inspection, new / increasing changes on follow-up) on axial T2-weighted images and analysis of altered diffusion with DWI.  Motor outcome.	<u>Median age at onset</u> of dystonia: 10M in both groups. More severe dystonia in patients with acute onset. <u>Striatal lesions</u> : acute-onset (n=11): extensive lesions, insidious-onset (8/10): restricted to dorsolateral putamen, acute-on-insidious (n=2) & insidious with progressive dystonia: extensive striatal changes superimposed on pre-existing dorsolateral putaminal lesions. <u>Latency phase</u> of 3.5 months to 6.5 years between detection and clinical manifestation of dorsolateral putaminal lesions in insidious-onset patients. → pre-symptomatic detection of relevant brain injury → detection of noduli potentially indicating a slow neoplastic process → surrogate of chronic neurotoxicity	no standardized follow-up intervals for MRI	Small sample (Imprecision)	2+	Monitoring
<b>Boy et al.</b> (2021) Genet Med 23: 13-21	Impact of newborn screening and quality of therapy on the neurological outcome in glutaric aciduria type 1: a meta-analysis	Meta-analysis  Systematic literature search for articles published from 2000 to 2019 using the PRISMA protocol. Studies reporting on more than one individual	<u>n=647 patients</u> (from 15 publications)  Patients identified by NBS vs. patients identified by targeted metabolic studies (diagnosis was made after the	Clinical outcome Neurologic outcome: complex MD with predominant dystonia, or ataxia, or with spastic para- or tetraparesis Onset type: acute / insidious Motor development: normal/abnormal according to age Treatment Mortality	- NBS group: 261 patients (n=171 HE, 53 LE, 37 unknown), TMS group: 386 patients (n=167 HE, 87 LE, 132 unknown) <u>Motor development</u> : patients identified by NBS showed a significantly higher proportion of normal motor development than TMS patients, TMS patients showed a higher rate of delayed motor development. - NBS group: 74,7% asymptomatic, 25,3% MD (n=66 patients, with n=39 acute onset, n=23 insidious onset), neurologic outcome did not differ between HE and LE patients, 9 patients died (7 with severe MD). - TMS group: 9,6% with unspecific clinical signs at diagnosis (without irreversible neurologic symptoms) vs. 90,4 % symptomatic with MD at diagnosis (69,9% acute onset, 22,6% insidious onset, 7,5% unknown onset); 81,7% with delayed		Heterogeneous data quality and number of reported variables  Small sample sizes of included studies (in most cases).	1+	Therapie  Monitoring

		identified by NBS were included.	onset of clinical symptoms )		<p>motor development, 18,1% of symptomatic patients died.</p> <p><u>Treatment:</u></p> <p>Patients not following maintenance treatment (low lysine diet and carnitine supplementation) guideline recommendations showed a trend for increased relative risk for insidious onset MD (complex movement disorder) compared to patients with recommended dietary treatment.</p> <ul style="list-style-type: none"> <li>- MT according to guideline recommendations in 71,8% (whole NBS group) vs. 51,5% (symptomatic NBS patients) and 49,6% (symptomatic TMS patients) vs. 29,7% (asymptomatic TMS patients).</li> <li>- ET according to guideline: 66,6% (asymptomatic NBS patients) vs. 72,7% (symptomatic NBS patients); data not available for TMS patients.</li> </ul> <p>→ motor development was more often normal in NBS patients than in TMS patients, with a lower frequency of MD</p> <p>→ survival did not differ between NBS and TMS patients</p> <p>→ trend for increased relative risk for insidious onset MD in patients not following MT recommendations</p> <p>→ increased relative risk for acute onset MD in patients with delayed ET</p>				
<p><b>Boy et al.</b> (2021) J Inherit Metab Dis 1-10. doi:10.1002/jimd.12436</p>	<p>Subdural hematoma in glutaric aciduria type 1: High excreters are prone to incidental SDH despite newborn screening</p>	<p>Retrospective evaluation for SDH, as part of the ongoing prospective study on long-term outcome of GA1 patients</p>	<p>N=69 patients with 168 MRI scans</p>	<p>Retrospective evaluation for SDH</p>	<p>168 MRIs of 69 patients with GA1 (age at MRI 9 days – 73.8 years, median 3.2 years)</p> <ul style="list-style-type: none"> <li>- SDH in 8 HE patients, imaged between 5.8 and 24.4 months</li> <li>→ space-occupying SDH in 2 patients after minor accidental trauma</li> <li>→ SDH as an incidental finding in 6 patients without trauma</li> <li>- patients without trauma imaged at 3 to 30 months (n = 36, 25 NBS, 27/9 high/low excreters): incidence of SDH was 16.7% (16% in NBS).</li> <li>→ SDH was more common after acute (33.3%) than insidious onset of dystonia (14.3%) or in asymptomatic patients (5.9%)</li> </ul>	<p>no standardized follow-up intervals for MRI</p>	<p>Retrospective design of the study</p> <p>Imprecision (low n)</p>	<p>2+</p>	<p>Monitoring</p>

					<p>→ SDH was only seen in patients with wide frontoparietal CSF spaces and frontotemporal hypoplasia.</p> <p>→ HE were over-represented among patients with SDH (6/27 vs 0/9 low excreters), acute onset (10/12), and wide frontoparietal CSF spaces (16/19).</p> <p>→ Incidental SDH occurs despite NBS and early treatment in approximately one in six patients with GA1 imaged during late infancy and early childhood. Greater risk of high excreters is morphologically associated with more frequent enlargement of external CSF spaces including frontotemporal hypoplasia, and may be furthered aggravated by more pronounced alterations of cerebral blood volume and venous pressure.</p>				
<b>Campos-Garcia et al. (2019)</b> Mol Genet Metab Rep; 21:100533	Characterization of novel GCDH pathogenic variants causing glutaric aciduria type 1 in the southeast of Mexico	Case series	n=5	Mutation analysis	<p>n=3 novel mutations: c.389T&gt;C, c.1108delC, c.1172G&gt;T</p> <p><u>Patient 1:</u> compound heterozygous (c.880C&gt;T + c.881G&gt;A).</p> <p><u>Patient 2+4:</u> homozygous (c.389 T&gt;C).</p> <p><u>Patient 3:</u> compound heterozygous (c.389T&gt;G + c.1108delC)</p> <p><u>Patient 5:</u> compound heterozygous (c.389T&gt;C + c.1172G &gt;T)</p>	Detection bias (small sample size)	Indirectness (population differences)	2-	Diagnostik
<b>Carling et al. (2020)</b> Int J Neonatal Screen 6:92	Evaluation of a Common Internal Standard Material to Reduce Inter-Laboratory Variation and Ensure the Quality, Safety and Efficacy of Expanded Newborn Screening Results When Using Flow Injection Analysis Tandem Mass	Methodology		Evaluation of the effect of stable isotope internal standard (IS) used for quantitation on inter-laboratory variation	<p>NBS programs in England and Wales now include four additional disorders: classical homocystinuria, IVA, GA1, MSUD.</p> <p>Post-implementation, population data monitoring showed high inter-laboratory variation with 90th centiles varying from 17% to 59%. → Four laboratories analysed routine screening samples (n &gt; 101,820) using a common IS. Inter-laboratory variation was determined for the eight analytes and compared with results obtained using an in-house common IS (n &gt; 102,194). A linear mixed-effects model was fitted to the data.</p> <p>→ Using a common IS mix reduced the inter-laboratory variation significantly (p &lt; 0.05) for five analytes. For three analytes, the lack of</p>		Indirectness (population differences)	2-	Diagnostik

	Spectrometry with Internal Calibration				significance was explained by use of individual laboratory "calibration factors". → For screening programs where laboratories adhere to single analyte cut-off values (COVs), it is important that inter-laboratory variation is minimized, primarily to prevent false positive results. Whilst the use of a common IS helps achieve this, it is evident that instrument set-up also contributes to inter-laboratory variation.				
<b>Chen et al. (2020)</b> Orphanet J Rare Dis 15:337	Audiological and otologic manifestations of glutaric aciduria type I	Observational, single center	N=13 (Taiwan) 12/13 NBS and 1/13 TMX, 2-26yrs	Pure tone average (PTA) by calculating the threshold of frequencies at 500, 1000, 2000 and 4000 Hz. no hearing loss = PTA was less than 16 dB HL, 16–25 dB HL was slight hearing loss, 26–40 dB HL was mild hearing loss, 41–55 dB HL was moderate hearing loss, 56–70 dB HL was moderately severe hearing loss, 71–90 dB HL was severe hearing loss, and ≥ 91 dB HL was profound hearing loss  Neurologic symptoms  Molecular genetic testing including targeted sequencing of 4 common genes related to deafness	3/13 had EC  2/13 seizure  Sensineural hearing loss in 76.9% (10/13), slight: n=6, mild: n=2, moderate: n=1  N=3 EC patients, not significant on hearing loss  ICU Patients (6/13) significantly more hearing loss (only significant risk factor variable)  4/13 asymptomatic patients without EC (#1, 2, 7, 12) had slight-mild hearing loss (2/4 had ICU treatment, ¼ had increased disability score after ICU)  MRI did not detect abnormal ENT causes  Macrocephaly had no impact on hearing function	Retrospective analysis Single center	Small study sample (Imprecision)  Treatment and treatment compliance not reported  Classification of symptomatic patients unclear  1 asymptomatic had EC?  1 asymptomatic had basal ganglia diffusion abnormality?  1 seizure patient had EC, but no dystonia?	2-	Monitoring

<b>Numata-Uematsu et al.</b> (2017) Brain Dev; 39(6):532-535	Reversible brain atrophy in glutaric aciduria type 1	Case report	n=1 female diagnosed by NBS	Brain MRI  Motor development (Head control, sitting, walking)  Mental development (not specified)  Concentrations of C5DC, lysin, tryptophan	- Motor development: Good head control at 4M, independent sitting at 8M, walking alone at 14M. Normal motor and mental development at 26M. - Brain MRI at age 4M: widened operculum with dilatation of subarachnoid spaces surrounding atrophic bilateral frontotemporal lobes. - Brain MRI at 17M + 26M: atrophic lesion had disappeared. - No metabolic decompensation episode reported, normal development. → Early dietary modifications with lower level of glutarylcarntine + administration of carnitine can lead to normal development.	Publication bias due to journals favoring positive outcome findings?  Findings from case reports cannot be generalized.	Case study (N = 1)  Authors don't specify how the "normal" mental and motor development was conducted, no tests or scores are cited.	3	Monitoring
<b>Patel et al.</b> (2018) JIMD Rep; 40:85-90	Early Diagnosed and Treated Glutaric Acidemia Type 1 Female Presenting with Subependymal Nodules in Adulthood	Case report	n=1	Neuroimaging in adulthood	Female patient with macrocephaly + megalencephaly leading to the suspicion of GA1. Diagnosis (biochemical + enzyme activity) at age 2M before the onset of symptoms. MT: low protein diet + carnitine + riboflavin. No metabolic crises as a child, normal neurological presentation, but learning difficulties in school. Headache at age 12Y: diagnosed as being migrainous + related to idiopathic intracranial hypertension. 2 successful pregnancies at age 23 + 25Y. At age 28Y: presentation after 3 weeks of slurred speech + left facial weakness + numbness. MRI at age 22/26/28Y: callosal + periventricular white matter changes, age discordant parenchymal atrophy, multifocal subependymal nodules in lateral ventricles. Genetic testing for tuberous sclerosis negative, confirmation of GA1 via mutation analysis. → subependymal nodules as natural progression of GA1 despite early diagnosis and metabolic control = surrogate of chronic neurotoxicity.		N=1  No detailed information about treatment,  First MRI not clearly described (postnatal?, no „nodules“ described)	3	Monitoring

<b>Peake</b> (2016) Clin Chem; 62(8):1159-1160	Seizures, Dystonia, and Spasms in a 14-Year-Old Child	Case report	n=1	Clinical outcome of late-diagnosed patient Biochemical analysis Mutation analysis	14Y male patient Medical history: basal ganglia stroke in infancy, hypoxic brain injury, dystonia, spasms. Treatment: Levetiracetam for seizure control. GC/MS: GA in urine 400 mmol/mol creatinine. Mutation analysis: homozygous c.1204C>T.			3	Diagnostik
<b>Peng et al.</b> (2018) Taiwan J Obstet Gynecol; 57(1):137-140.	Prenatal diagnosis of fetal glutaric aciduria type 1 with rare compound heterozygous mutations in GCDH gene	Case report	n=1	Prenatal diagnosis	22Y female, Gravida 4, Para 2 - First child: healthy - Second child: diagnosed with GA1 by NBS - Prenatal examination at 13-19 weeks of gestational age: Maternal IVS3+1G>A, paternal c.1240G>A. - Termination of pregnancy.		Indirectness (population differences)	3	Diagnostik
<b>Peng et al.</b> (2020) Int J Neonatal Screen; 6(1):16	Reducing False-Positive Results in Newborn Screening Using Machine Learning		n=2777 screen-positive babies (of which n=2542 false-positive).	False-positive results in NBS for four metabolic diseases: GA1, MMA, OTCD, VLCADD	<u>Aim:</u> Random Forest machine learning classifier on screening data to improve prediction of true and false positives. <u>Data</u> included 39 metabolic analytes detected by MS/MS + clinical variables such as gestational age and birth weight of n=2777 screen-positive babies (of which n=2542 false-positive) for GA1, MMA, OTCD, VLCADD. <u>Results:</u> Without changing the sensitivity to detect these disorders in screening, Random Forest-based analysis of all metabolites reduced the number of false positives for GA-1 by 89% (48 confirmed positive vs. 1344 First-Tier NBS false-positive vs. 150 Second-Tier (this study) false-positive). - Random Forest's ability to classify GA-1 false positives was found similar to results obtained using Clinical Laboratory Integrated Reports (CLIR). - Development of an online Random Forest tool for interpretive analysis of increasingly complex data from newborn screening.		Indirectness (population differences)	3	Diagnostik
<b>Peng et al.</b> (2020) J Inherit Metab Dis; 10.1002/jimd.12236	Ethnic variability in newborn metabolic screening markers	Retrospective study	n=100.000 screen-negative babies + n=2767 screen-	False-positive results in NBS for four metabolic diseases: GA1, MMA, OTCD, VLCADD	Analysis of screen-negative babies (n = 100 000) (blood metabolic markers measured by MS/MS and ethnicity status reported by the parents). Comparison of metabolic marker levels between major ethnic groups (Asian, Black, Hispanic, White) using		Indirectness (population differences)	2+	Diagnostik

	associated with false-positive outcomes		positive babies (of which n=2532 false-positive)		effect size analysis, which controlled for group size differences and influence from clinical variables. Correlation of marker level differences found between ethnic groups to NBS data from 2532 false-positive cases for four metabolic diseases: GA1, MMA, OTCD, VLCADD. 79% of the metabolic markers (34 of 43) had ethnicity-related differences. Black infants had elevated GA1 markers (C5DC, Cohen's d = .37, P < .001), and also higher false-positive rates for GA1.				
<b>Piercy et al. (2019) BMC Pediatr;</b> 19(1):349	What are the information needs of parents caring for a child with Glutaric aciduria type 1?	Qualitative study design, focus group with five parents (4 mothers and 1 father) of four children with GA1, one focus group discussion	Focus group with five parents of four children with GA1 (17y, 8y, 3y, 2y) - older children had been diagnosed clinically, younger children diagnosed through NBS	Gain insight into the information that parents needed and the ways in which they accessed and used information to manage their child's condition.	Two themes were identified: "understanding the condition" and "managing the condition"  <b>understanding the condition:</b> parent's need to understand the scientific complexity of the condition and be aware of the worst case scenario associated with the loss of metabolic control.  <b>managing the condition:</b> how parents coordinate and control the involvement of other carers and parents' need to be active partners in medical managements.	Selection bias: Recruitment process of the parents: parents of children with GA1 from a regional metabolic center and via a national parents' metabolic support organization. Parents were approached by their clinician or by an organizer of the support group.	Study limitations: small group (n = 5) with children diagnosed by two different ways.  No demographic information about the families collected.  Only one focus group conducted	3	Monitoring

<b>Sanju et al.</b> (2021) J Pediatr Intensive Care; 10:65-70	Glutaric Aciduria Type 1: A Case Report and Review of Literature	Case report	n=1	Neuroradiologic imaging	8M male - referred with history of fever, convulsions, dystonic posturing, altered sensorium, loss of motor and mental milestones since 1M - MRI brain: frontoparietal atrophy, "bat-wing appearance," basal ganglia changes - Carnitine + acylcarnitine profile: low total carnitine, very low free carnitine, and low free/acylcarnitine ratio, normal levels of plasma amino acids. - Urine gas chromatography mass spectrometry: elevated level of ketones (3-hydroxybutyric acid and acetoacetate) and glutaric acid with the presence of 3-hydroxyglutaric acid. - Diet modification and pharmacotherapy with riboflavin and carnitine arrested the neurological deterioration in the patient.		Indirectness (population differences)  Imprecision (small sample size, only one patient)	3	Diagn ostik
<b>Sarangi et al.</b> (2017) J Pediatr Neurosci; 12(1):85-86	Glutaric Aciduria Type I: A Rare Metabolic Disorder Mimicking as Choreoathetoid Cerebral Palsy	Case report	n=1	Neuroradiologic imaging Biochemical analysis	7Y male - Choreoathetoid movements of upper & lower limbs, dystonia, slurring of speech since age 1;6Y - Born after uncomplicated pregnancy, no consanguinity, no history of birth asphyxia or jaundice during infancy. - History of generalized tonic– clonic convulsion following febrile illness at age 1;6Y - Involuntary movements started following the episode of seizure. - <u>Exam</u> : head circumference: 58 cm (>97th centile, macrocephaly), conscious, well oriented, dysarthria, hypotonia in both upper + lower limbs,		Indirectness (population differences)  Imprecision (small sample size, only one patient)	3	Diagn ostik

					diminished reflexes, generalized choreoathetosis, dystonia of both upper + lower limbs. MRI (Axial T2-weighted): bilateral frontotemporal atrophy, wide Sylvian fissure ("bat-wings") - <u>Confirmation of GA1</u> through MS/MS + GC/MS. - <u>Treatment</u> : Riboflavin, carnitine, protein-restricted low-lysine/ low-tryptophan diet - Follow-up after 3M: some reduction in involuntary movements.				
<b>Schillaci et al.</b> (2016) Mol Genet Metab; 119(1-2):50-56	The M405V allele of the glutaryl-CoA dehydrogenase gene is an important marker for glutaric aciduria type I (GA-I) low excretors	Case report + case series	n=9 LE patients + n=5 HE patients (+1 GA2 patient)	Mutation analysis Biochemical analysis including urinary C5DC Clinical outcome	<u>Patient 1</u> : first evaluation at 1Y due to developmental delay, failure to thrive, dystonic posturing, hypotonia, brain MRI showing basal ganglia changes. Mutation analysis: M405V, V133L (novel). <u>Patient 2</u> : acute onset of symptoms at 5,5M with left sided hemiparesis with spasticity during inter-current illness. Brain MRI: increased signal bilaterally in basal ganglia. Mutation analysis: M405V, V400M. Treatment: low-protein diet, riboflavin, carnitine. Severe MD at age 11Y. <u>Patient 1-9</u> : compound-heterozygous for M405V with GCDH activity of 4-25%. - 3 patients screened by NBS, of which 1 patients was missed by NBS - 6 patients not screened by NBS developed acute striatal necrosis within the first year of life. <u>Patient 1-15 (10-15 = 5 HE + 1 GA2)</u> : linear relationship between plasma C5DC + urinary C5DC → urinary C5DC as a specific marker for GA1, especially for patients with normal urine organic acids + plasma acylcarnitine profiles.		Small sample size	2-	Diagnosis
<b>Schmidt et al.</b> (2020) J Inher Metab Dis; 10.1002/jimd.12233	Impact of enteral arginine supplementation on lysine metabolism in humans: A proof-of-concept for lysine-related inborn errors of metabolism	Proof of concept study Measurement of oxydation of a stable isotope tracer L-(1.13C)lysi	n=5 healthy men (age 22-25 years)	Impact of enteral arginine supplementation on lysine metabolism, lysine oxidation and lysine plasma concentrations	- Increasing doses of L-arginine Hydrochloride caused a linear decrease in whole-body lysine oxidation. Plasma arginine concentration increased, plasma lysine concentration decreased below normal range with high arginine intakes. - Results suggest 300-600 mg/kg/d of L-arginine Hydroxychloride + lysine intake restricted to DRI is needed to reduce enteral lysine uptake + systemic lysine oxidation. Whole-body lysine oxidation and plasma lysine concentrations decreased	Age, Gender only effect on plasma amino acid examined, not on CSF levels and/or lysine influx across BBB	Only healthy individuals, no patients	3	Therapie

		ne to 13 CO2 in response to ingestion of a single oral administration of arginine (50-600 mg/kg/d)			significantly with increasing dosage of oral arginine intake. Approx. 300-600 mg/kg/d of oral arginine are needed to reduce systemic lysine oxidation	Selection bias (only 1 group)
